TITLE: Free radicals of a new type in yeast cells

SOURCE: Biofizika, v. 10, no. 1, 1965, 167-168 22

TOPIC TAGS: yeast, free radical

ABSTRACT: An EPR signal of a new type was detected in tests on *Saccharomyces cerevisiae*, *Saccharomyces carlsbergensis*, and *Monilica murmanica*. The signal was an incompletely resolved doublet with a half-width of ~ 40 gauss, a g factor of 2.03 at the absorption maximum, and an intensity corresponding to 10^5 spins per cell of *Saccharomyces cerevisiae*. The magnitude of the g factor and the relation between the intensity and the temperature indicated that the signal was due to the presence of organic free radicals with the unpaired electron at a sulfur atom. The authors thank L. A. Blyumenfel'd for his interest in this work and for his valuable advice. Orig. art. has: 2 figures.

TITLE: A Stereotopographical Experimental Survey of an Alpine Region
on a Scale of 1 : 25 000 (Opytnaya rabota po stereotopografi-
cheskoy s"yemke vysokogornogo uchastka v mashtabe 1 : 25 000)

PERIODICAL: Geodeziya i kartografiya, 1958, Nr 7, pp. 14-26 (USSR)

ABSTRACT: An experimental survey of an alpine region on a scale of
1 : 25 000 was carried out at the stereoprojector **SPR-2**
of the TsNIIGAIK (Central Scientific Research Institute of
Surveying, Aerial Photography and Cartography). The purpose
of this work was to determine the scope of application of
this apparatus and to work out suggestions for a representa-
tion of mountainous territory. Research pushed in this direc-
tion has not yet been concluded. This is a presentation of
the results. The area and the sources for surveying are de-
scribed. The section to be mapped is a typical alpine re-
gion with elevations reaching 4 000 m. The area covered by

Card 1/3

807/6-58-7-3/19

A Stereotopographical Experimental Survey of an Alpine Region on a Scale of 1 : 25 000

the survey was 100 km². The aerial photographs were taken on a scale of 1 : 40 000 with the aerial camera TE with a focal length of $f_k = 100\text{mm}$, an end overlap of 70-85 % and a side overlap of 40-70 %. The whole area of the section was covered by twelve aerial photographs, 232 control points were established. The second passage describes the stereo-photogrammetric work and their succession. Some particular features in the orienting of aerial photographs of alpine territory of the work with the **SPR-2** are mentioned. The determination of the coordinates of points in the terrain and the estimation of the accuracy is mentioned. This equipment guarantees the required accuracy. In a table the accuracy of this and of other apparatus is compared. The surveying of soil elevations and of the contours is described and some practical suggestions are made. The third passage deals with the presentation of the elements of alpine territory in the original plotting map. Shortcomings occurring in the presentation are indicated. It is shown that a correct and accurate presentation is less dependent on the elevation in the cross-section than upon the technique of conducting

TITLE:

Stereotopographic Survey of Mountain Areas on Scales of
1 : 10,000 and 1 : 25,000 (Stereotopograficheskaya s'yemka
gornyykh rayonov v masshtabakh 1 : 10,000 i 1 : 25,000)

PERIODICAL:

Geodeziya i kartografiya, 1959, Nr 6, pp 14-20 (USSR)

ABSTRACT:

In the regulations for topographic surveys on scales of
1 : 10,000 and 1 : 25,000, an aerial survey on two scales is
provided for the preparation of maps of mountain areas by the
stereotopographic method. The investigations carried out by the
author in the photogrammetric laboratory of the TsNIIGAIK are
described here. Aerial surveys on two scales were used for the
stereotopographic survey of a mountain area. The site of in-
vestigations is a mountain area of mean altitude with absolute
heights of 1250-2000 m, which is broken up by deep valleys and
rivers. The slopes have a gradient of 18-30° and are wooded in
part. Aerial surveys on small scales of 1 : 62,000 ($f_k=70$ mm),
1 : 44,000 ($f_k=70$ mm) and on large scales of 1 : 16,000
($f_k=200$ mm), 1 : 21,000 ($f_k=200$ mm) were used as initial

Card 1/3

Stereotopographic Survey of Mountain Areas on
Scales of 1 : 10,000 and 1 : 25,000

SDV/6-59-6-3/22

references. The aerial surveys were made in 1953 by means of the aerial camera AFA-Te. After setting up the technical working project, the photogrammetric determination of heights and positions of points was carried out according to the small-scale air surveys, as well as the stereophotogrammetric evaluation of large-scale air surveys. This work is described here. The photogrammetric determination of height was made on the stereoprojector SPR-2 and on the stereometer STD-2. To avoid errors, the measurements were carried out independently by Vanin and Petrosova on SPR-2, and by Petrosova and Semenova on STD-2. Before starting the stereoscopic drawing of the relief, the accuracy of the photogrammetric determination of height was evaluated according to geodetic control points. The results are given in table 3. The root mean square error of the point position was 13.7 m. and the maximum error was 310.0 m. To determine the efficiency of the method described here, it was compared with the usual method for air surveys in one scale, with respect to technical-economic characteristics. The results are shown in table 4. They indicate that costs are reduced by about one-half by using the method described here.

Card 2/3

Stereotopographic Survey of Mountain Areas on
Scales of 1 : 10,000 and 1 : 25,000

S07/6-59-6-3/22

The investigations carried out show that the use of air surveys in small scale (1 : 62,000) ensures a sufficient accuracy. For surveys in scale of 1 : 25,000 with the use of SPR-2, air surveys in smaller scale (1 : 70,000) can be used. The reliability of identification at a ratio of 1 : 5 to 6 of the air survey scales is quite real for completion on SPR-2. A comparison of data in the evaluation on SPR-2 and STD-2 shows that better results, with respect to accuracy and working capacity, are obtained by completion on SPR-2. For completion from small-scale air surveys on SPR-2, the diameter of the floating mark must be reduced, and a coordinatograph (Koordinatograf) (Fig 2) must be prepared for the device (as it is not supplied with the device). The evaluation of small-scale air surveys puts higher requirements to the quality of air surveying material and the quality with respect to accuracy of the film. By the use of small-scale air surveys, the number of points in the field compilation survey is reduced considerably. There are 5 figures, 4 tables, and 2 Soviet references.

TOPIC TAGS: photogrammetric network, statoscope, aerophotograph, geodetic point,
photogrammetric point, standard position, triangulation, GEODETIC SURVEY,
PHOTOGRAMMETRY

ABSTRACT: Two kinds of photogrammetric networks are analyzed. One network is
independent and the other is compiled from data obtained with an instrument is
equipped with a base component determined from statoscope readings. The free net-
work yields a spatial model of landscapes from a spheroid covered by aerophotographs.
This network, if oriented on geodetic points, differs from aerial maps because of the
difference between geodetic and photogrammetric planes. The difference in point
altitudes increases with the increase of the network area. When aerial photographs

Card 1/2

UDC: 528.735.4 : 528.716.2

ACC NR: AT6028595

are obtained under equal isobaric and level conditions using a statoscope, then photogrammetric and geodetic altitudes of basic points at the network boundary are equal. In the middle of the network, photogrammetric points are higher than geodetic points. The compiling of a spatial photogrammetric network on the basis of real photographs is difficult and complicated because of errors in photographs caused by shifting of base points, by disagreement of isobaric and level surfaces, and errors in statoscope readings. Systematic errors in photographs distributed symmetrically influence the point position similar to Earth's curvature. Different values of altitude deviations occur when the side points are shifted from the standard position. Asymmetric errors may be caused by low quality of the instrument lenses resulting in distortion. It is not expedient to compile independent photogrammetric networks for large areas. Small-scale photographs are not effective because systematic errors and the Earth's curvature cause distortion of the relief. Orig. art. has: 2 figures, 2 tables, and 6 formulas.

TITLE: Development of traverse photogrammetric networks of large dimensions using a stereoprojector and stereograph

SOURCE: Moscow. Tsentral'nyy nauchno-issledovatel'skiy institut geodezii, aeros"-yemki i kartografii. Trudy, no. 165, 1966. Issledovaniya po fotogrammetrii (Research in photogrammetry), 23-55

TOPIC TAGS: photogrammetric network, atmospheric refraction, photogrammetric coordinate, statoscope, azimuth, ~~photogrammetric~~, base point, stereograph, *photogrammetry, photographic material, photographic processing*

ABSTRACT: The accuracy of a photogrammetric network is decreased by atmospheric refraction, faulty lenses of the aerial camera, by errors of photogrammetric coordinates, and by methodic errors in processing observational data. Some errors may be eliminated by the use of statoscope readings. Experimental data showed that the main distortion is caused by damage to photographic materials during laboratory processing of films. Formulas were developed for computation of laboratory processing errors and their influence on the final result. The composition of a photogrammetric network from individual links contains errors introduced by erroneous azimuths of

Card 1/2

UDC: 528.735.4

ACC NR: AT6028596

individual links. These errors are positive when points of the network are shifted to positive ordinates. Formulas for correction of these errors are developed. Coefficients for coordinate transformation can be determined from measured discrepancies of coordinates of base points. Formulas for coefficients are compiled for meridional and latitudinal directions. Remaining errors in network deformations after coordinate transformations influence the position of base points and the scale of maps. The accuracy of traverse networks compiled from stereoprojector and stereograph data is influenced by errors introduced by orientation of links and scale determination, which depend upon the stadiometer readings and the coordinates of the model points. Results of hphotogrammetric networks compiled satisfy claims of relief sections of 5 m for flat regions. Orig. art. has: 9 figures, 14 tables, and 55 formulas.

TITLE: A graphic method for computing the effect of atmospheric refraction and the curvature of the earth

SOURCE: Geodeziya i kartografiya, no. 1, 1967, 34-40

TOPIC TAGS: atmospheric refraction, aerial photography, aerial triangulation, error correction, multimeter

ABSTRACT: A graphic method for computing the effect of atmospheric refraction and the earth's curvature on aerial photographs is presented. It can be used when correcting individual stereo pairs and constructing 3-dimensional phototriangulation networks with the help of multimeters without systematic error compensators. To obtain good results, the difference in the heights of the points in the photographs must be $< 1/15$ of the height from which the photograph was taken (H). The refraction and curvature effects on the distance of a point from the principal points (r) are easily calculated, leading to δr_r and δr_c , the point coordinate errors (δx , δy), and the longitudinal and transverse parallax (δp and δq). The correction for the heights of points from δp is

Card 1/2

UDC: 528.061.2+528.061.3:528.735.4

ACC NR: AP7007315

$$\delta h_{p_i} = - \left\{ \frac{H}{b} \left(\frac{x_l}{r_l} \delta r_l - \frac{x_n}{r_n} \delta r_n \right) + \delta h_{p_{on}} \right\},$$

where b is the base value, and the last term gives a correction for the reference point height error (subscripts l and r refer to left and right). The mutual orientation ($\Delta\alpha$) is distorted by δq . With standard point spacing, the resulting height error is

$$\delta h_{\Delta\alpha} = - \frac{2Hx_l(b-x_{lr})}{b^2} \left(\frac{\delta r_l}{r_l} - \frac{\delta r_n}{r_n} \right).$$

Tables for cameras with focal lengths of 70 and 100 mm and H of 1.0—6.0 km are presented for ease in constructing nomograms of correctional isolines based on the above formulae. Details of the construction and an example of work are given. Objective lens distortions and errors resulting from deviations of the camera film holder clamping surface from a flat plane can be similarly corrected for if they have a radial and symmetrical character and are accurately known. Orig. art. has: 2 figures, 4 tables, and 7 formulas. [04]

TOPIC TAGS: dielectric constant, anisotropic medium, statistic physics

ABSTRACT: The published methods of calculating the average dielectric constant in disordered inhomogeneous systems are reviewed. A detailed analysis is made of the method of juxtaposition (juxtaposition of an individual chosen particle with the system of remaining particles which are represented as a continuous medium having the sought value of ϵ). It is shown that this method can be extended to statistical mixtures and is not applicable directly to cellular systems. The concept of the statistical system is generalized. By regarding a system such as a suspension as a special case of a statistical system and by generalizing and refining the method of juxtaposition, the author derives an approximate formula for the values of ϵ of inhomogeneous systems of the suspension type. The calculated formula was confirmed experimentally with two-dimensional models made of conducting paper. V. Sarafanov.

<p>Combating pests and diseases of berries. J. I. Vania. <i>Sady i Ogorody</i> (U. S. S. R.) 1941, No. 4, 24-5. --The autumn methods of combating mildew and currant Rupresidiae of gooseberries include the trimming of the diseased twigs, dusting with 3% FeSO₄, and disinfecting the grafts by immersing them for 5 min. in 1% CuSO₄, and washing. In spring the plants are sprayed with 1% Bordeaux mixt. against spring rust and with 0.1% Ca₂(AsO₄)₂ against mildew. After blossoming the gooseberries are again sprayed with 0.1% Ca₂(AsO₄)₂ against mildew and with 0.2-0.3% Ca₂(AsO₄)₂ against the gooseberry Perilobular larvae. The spraying against mildew is repeated after every 10 days until 20 days before harvesting. During harvesting the gooseberries are sprayed with 0.1% Ca₂(AsO₄)₂ against mildew and with 0.2% Ca₂(AsO₄)₂ or Paris green with a double amt. of lime against Tenthrinidae. Similar methods are recommended against the pests and diseases of currants. The raspberry buds are sprayed with 0.2% Ca₂(AsO₄)₂ or 0.15% analbasine sulfate with 0.4% soap against the raspberry bud moth or Aphididae. Spraying with 0.7% NaSiF₆ is used against the raspberry Curculionidae. The spraying is repeated after 8-10 days. During blossoming of the raspberries they are dusted with 5-7% analbasine or 5% woodash (approx. 10 kg. hectare), or sprayed with 0.2% analbasine sulfate plus 0.1% soap or with 1% milk of lime. The opening strawberry buds are sprayed with 1% Bordeaux mixt. and 0.1% Ca₂(AsO₄)₂ or with 0.15% Paris green. After harvesting the leaves are sprayed with 1% Bordeaux mixt. against white spots of the leaves. W. R. Henn.</p>		<p>CA</p>

<p>AM</p> <p>VANINE (S. I.). Методы фитопатологического исследования грибовых болезней леса и древесины. [Methods for the phytopathological investigation of fungal diseases of forest trees and timber.]—<i>Morbi Plantarum</i>, Leningrad, xvii, 3-4, pp. 129-132, 2 figs., 1928. [German summary. Received August, 1929.]</p> <p>In this paper a brief outline is given of the methods that have been devised at the A. A. Jaczewski Phytopathological Laboratory in Leningrad for the phytopathological survey of forest trees and of timber materials, with special references to diseases of fungal origin. Forest trees are divided into three classes, namely, nursery seedlings, young plantations, and mature stands, and a general characterization is given of the diseases proper to each class, together with brief instructions regarding the methods for making records of the pathogenic organisms or other causes of disease, of their incidence, and all other relevant data. In respect of mature stands, the method adopted is a combination of the system used in private silvicultural practice and that employed in state forest taxation practice. The role of felled timber are considered under three headings, namely, industrial timber in storage, firewood, and constructional timber in buildings.</p>

AM		VANSIE (S. L.) Главнейшие грибные болезни Бузулукского бора Самарской губернии. [Chief fungal diseases of the Bouzoulouk forest in the Samara Government.]— <i>Materials for Mycol. and Phytopath.</i> , Leningrad, viii, 1, pp. 238-255, 2 figs., 1 map, 1929. [Received September, 1930.]			
The results of a phytopathological survey in 1926 and 1927 of the extensive Bouzoulouk forest in the Samara Government [east Russia] showed that the most widespread disease of older stands of conifers was heart rot caused by <i>Trametes pini</i> , which in some places affected 68 per cent. of the trees. Considerable space is given to a discussion of the spread of the rot inside the trees and of the injury it causes to the timber, as well as of the measures that should be applied for its eradication. No direct correlation was noted between the incidence of the fungus and environmental conditions, but there were indications that it occurred somewhat more frequently in mixed stands, where conditions of growth were more favourable. Younger stands of conifers suffer rather severely from attacks of <i>Phacidium infestans</i> which, in some places, kills large numbers of one- to three-year-old trees [<i>R.A.M.</i> , viii, p. 475].		The chief diseases of broad-leaved species in the forest are <i>Fomes igniarius</i> on the aspen [<i>ibid.</i> , viii, p. 411; ix, p. 368], and <i>Polyporus dryophilus</i> (usually described from Russia under the name <i>P. dryoleus</i>) [<i>ibid.</i> , vii, p. 415] on oak.

VANINE (S. I.). Курс лесной Фитопатологии. Часть I. Болезни и повреждения вызываемые грибами. [Lectures on forest pathology. Part I. Diseases and injuries caused by fungi].— 326 pp., 159 figs., Госуд. С.-холодств. Науч. [State Agric. Publications Office], Moscow and Leningrad, 1931.

This useful and copiously illustrated publication is primarily designed to be a text-book for Russian students of forest pathology. It deals with the fungal diseases of trees and the timber decays caused by fungi which are of economic importance and are known

to occur on the territory of the Union of Russian Republics. Control measures, where applicable, are discussed under each disease. A list of the diseases arranged by their hosts and a list of alternate hosts for the rusts dangerous to trees are given at the end of the volume, and the bibliography appended occupies 18 pages.

VANINE (S. I.). Грибные повреждения бука (*Fagus orientalis*) и влияние их на качество древесины. [Fungal decays of the Beech (*Fagus orientalis*), and their effect on the quality of the wood.]—*Scient. Papers Inst. Engin. of Ways of Communication in Leningrad*, 111, 39 pp., 15 figs., 1932.

In this paper the author gives a brief account of the symptoms of the chief fungal rots that attack the beech (*Fagus orientalis*) in the Union of Soviet Republics, and also brief morphological descriptions of 24 species of Basidiomycetes usually found in association with these rots. Short diagnoses in Russian are further given of seven species of fungi that cause discoloration of beech timber, namely, *Hispora monilioides* Cda., *Styranus demanites* [cf. *R.A.M.*, xi, p. 80], *Bulgaria polymorpha* [ibid., viii, p. 425], *Lusiothraeria hispida*, *Trematosphaeria hyalrella*, *Rosellinia ambigua*, and *R. pulveracea*. Considerable space is given to a discussion of the physical and mechanical properties of sound beech wood, and of those of the timber in various stages of decay.

VANINA, S. I.

AM

VANINA (S. I.), ANDREYEV (I. E.), VLADIMIROVA (M. N. N.), & Sokolov (D. V.). *Домовые грибы и консервация древесины*. [House fungi and timber preservation.] -- Pamphlet issued by *Ленинск. обл. Республикан. Учен. Комитет*. [Leningrad Branch of Pan-Soviet Inst. for Building], Leningrad, 80 pp., 23 figs., 2 graphs, 1933.

The first of the three chapters into which this pamphlet is divided opens with an account of experiments, the results of which showed that the external mycelium of *Merulius laevis* and *Coniophora cerebella* is killed by 24 hours' exposure to an atmosphere containing 0.0052 gm. acetic acid or 0.033 gm. chlorine, or for one hour to one containing 0.1 gm. chloro-pyridin, in 1 l. air. The lethal action of sulphur dioxide and formalin was less pronounced, and such substances as carbon disulphide, benzol, benzene, and sulphuric ether had a still weaker effect on the mycelium. Further tests showed that all these substances diffuse very slightly in a radial direction in dry timber, and only acetic acid and formalin penetrated to a depth of 8 mm.

The remainder of this chapter and the whole of the second reproduce papers by the individual authors on certain points in the biology and activity of the house fungi, the contents of which have been noticed from other sources [see preceding abstracts]. The third chapter deals with the practical side of timber [chiefly pine and fir] impregnation with fungicides.

VANINE (S. I.). Синевая древесина и меры борьбы с ней. [Blue stain of timber and measures for its control.]. 104 pp., 48 figs., 10c. иллат. С.-х. и Лесно-х. н. Изд-во. Издательство [State Publishing Office of Agric. and Collective Farming Co-operative Literature], Leningrad, 1932.

This is a monograph, compiled from Russian and foreign researches, of the various fungi associated with the so-called blue staining of timber in the northern hemisphere. Of the 42 species briefly described and illustrated, the following appear to occur within the Russian Soviet Republics [cf. *R.A.M.*, x, p. 143], namely: *Ceratostomella burti* on boxwood [*Buxus* sp.]; *C. castaneae* on chestnut, oak, and beech; *C. coerulescens*, *C. piceae*, and *C. pinis* on conifers; *Lasiophtheria aspidiotum* on the wood of broad-leaved trees; *Rosellinia abietina* var. *trichota* on coniferous timber; *R. pulveracea* on broad-leaved species, especially oak timber; *Apophtheria petersii*, found sporadically on telegraph poles; *A. pinis*, frequent on standing dead pines killed by forest fires and causing a deeply penetrating bluish-grey discoloration of their wood; *Lignella pinicola* on windfalls of coniferous trees; *Coniophthium dispersellum* on pines and firs; *Cladoporium herbarum* on coniferous timber; *Hormiscium antiquum* on birch and other deciduous timber; *Hormonema dematioides* very frequent on pine and fir logs kept for a long time in the forests; *Sirodonium granulosum* on old chestnut and other deciduous timber; *Sporodermium chlosporii* on coniferous wood; *Trichosporium ligni-*

colum on pinewood; and *T. tingens* very frequent on aspen timber.

The remainder of the paper is a summarized account of the behaviour of the various fungi under natural and controlled conditions, and of the damage done by them to timber. Control measures, most of which are of a preventive nature, are discussed in considerable detail, and recommendations are given for the handling of the logs from the time of their felling to their industrial application.

VANISE (S. L.) & KOTCHIKINA (Mme E. M.). Методы фитопатологического исследования семян древесных пород. [Methods of pathological investigation of the seeds of arboreal species.]—*Bull. Leningrad Inst. for Controlling Farm and Forest Pests*, 2, pp. 285-297, 3 figs., 1932. [English summary.]

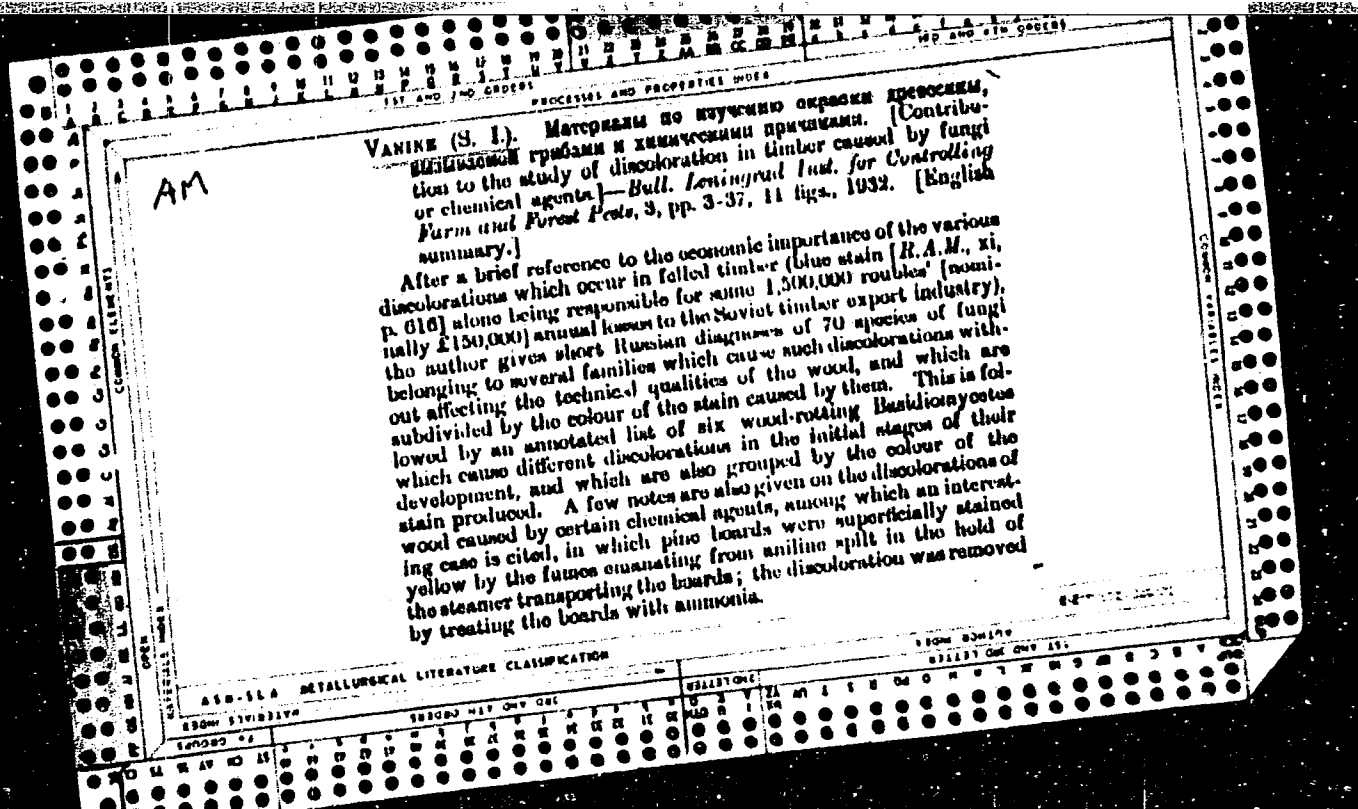

After stressing the importance from the phytopathological standpoint of determining the micro-organic flora present on the seeds of arboreal species, with particular reference to forest trees, the authors describe two methods for this purpose, one which is the usual method of planting out the seed on agar in Petri dishes, and the other consists in washing a given number of the seeds in a determined volume of sterilized water, and plating out a determined volume of the rinsings on agar. The latter method is most suitable for large-sized seeds, such as acorns, chestnuts, and the like, and allows of calculating the total number of fungal spores present in a sample from the number of colonies produced on the agar plates.

VANINE (S. L.) & VLADIMIRSKAYA (Mme N. N.). К вопросу о влиянии некоторых зазоров на развитие домовых грибов в древесные постройки. [The effect of certain constructional fillings on the development of house fungi in constructional timber.]—*Bull. Leningrad Inst. for Controlling Farm and Forest Pests*, 3, pp. 89-93, 1932. [English summary.]

The results of the experiments briefly reported in this paper showed that of the materials commonly used in Russia to fill in the constructional interspaces in buildings (floors, ceilings, partition walls), clinker [scoriaceous residuo from the combustion of coal, coke, and the like] and demolition rubble offer a greater resistance to the penetration of *Merulius lacrymans* and *Coniophora cerebella* from the surrounding timber than earth, clay mixed with straw, or sand. Lime and gravel proved to be practically impenetrable to these fungi, the latter chiefly owing to its very low water-holding capacity. The mycelium of *M. lacrymans* was shown to penetrate the fillings most readily at humidities of the environmental air approaching the saturation point, and a direct relationship was observed between the water-holding capacity of the filling material and its penetrability to either fungus.

PROCESSES AND PROPERTIES OF WOOD
VANINE (S. I.), ANDREEV (I. E.), & SOKOLOFF (D. V.). О влиянии
деревоуничтожающих грибов на древесину, окрашенную масляными крас-
ками и лаками. [The action of wood-destroying fungi on
wood coated with oil paints and varnish.]—*Bull. Leningrad
Inst. for Controlling Farm and Forest Pests*, 3, pp 45-50,
1 fig., 1 graph, 1932. [English summary.]

A brief account is given of controlled experiments, the results
of which [given in the form of tables] showed that pine wood
impregnated or coated with creosote was not decayed to any
visible extent at the end of three months from its inoculation with
Merulius lacrymans, *Coniophora cerebella*, or *Fomes pinicola*. All
the commercial oil paints or varnishes tested gave only partial
protection against invasion of the wood by these fungi; the
samples coated with white lead or zinc white, or with alcohol
varnish were considerably less decayed than the others. Sub-
sidiary experiments indicated that the controlling effect of the
coatings is not due to any inhibitive action exerted by the paints
or varnishes on the development of the fungi, but rather to the
fact that they reduce the hygroscopicity of the wood, and also
offer a mechanical barrier to the penetration of the organisms.
Much of their protective effect depends on the thickness and con-
tinuity of the layers in which the paints or varnishes are applied.

YASIN (S. I.) & YADIMIRSKAYA (Mme N. N.). K. 60800000
 200000000000. [Contribution to the biology of house-fungus]
 Bull. Leningrad Inst. for Constructing Farm and Forest
 Tech. 3, pp. 27-34, 4 figs., 1932. [English summary]

The investigation reported in some detail in this paper was
 made to throw light on some obscure points in the biology of
Mutinus leucomus and *Chromophora cerebella*. In mixed cultures
 of the two fungi on agar, at first the two organisms developed
 normally, without exerting any visible effect on each other, but
 when contact between the colonies was reached, *M. leucomus* had

458-52.6 METALLURGICAL LITERATURE CLASSIFICATION

1100 070159
 041133 041 000 151

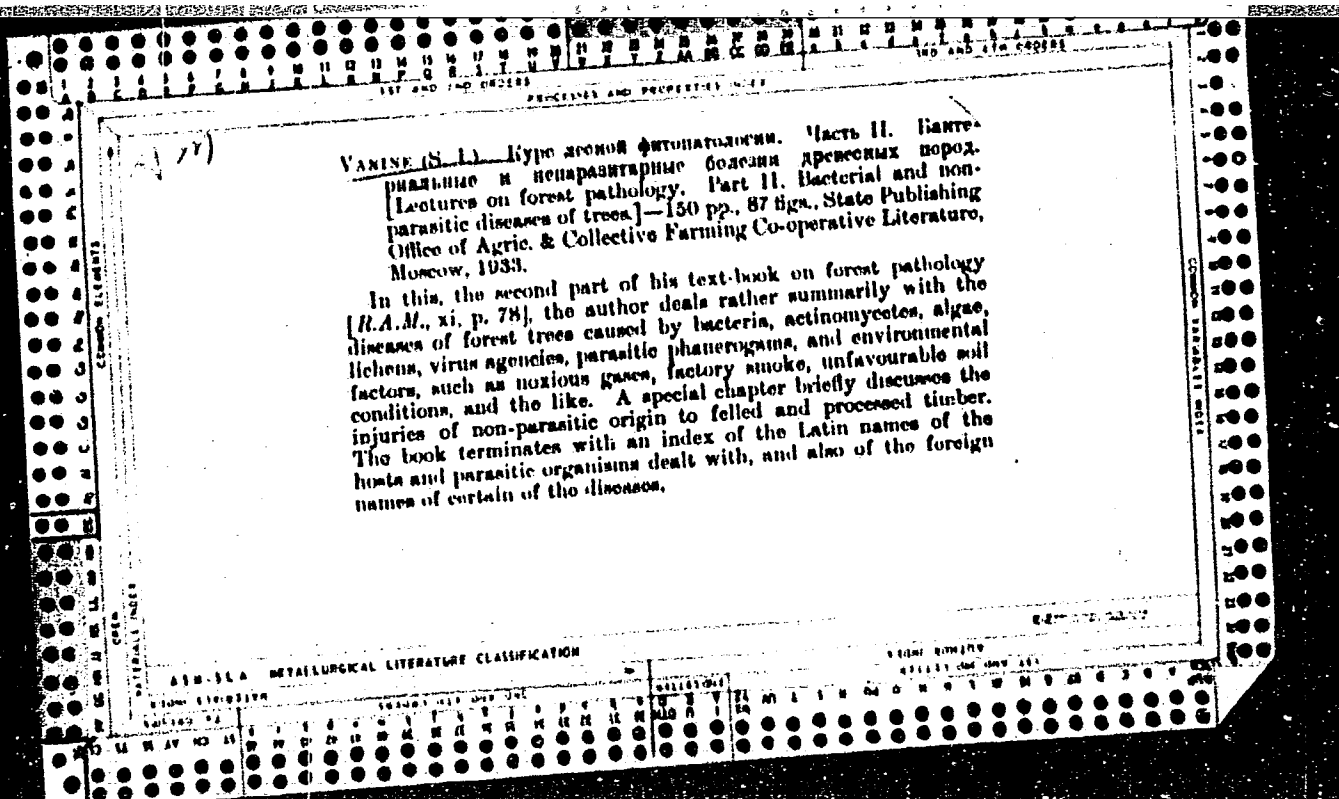

a depressing effect on the growth of *C. cerebella* (as shown by the latter's mycelium assuming abnormal forms), and finally overgrew it. In wood [species not stated] artificially inoculated with a mixture of the two fungi, the rot produced was very slightly greater (well within the limits of experimental error) than that caused by either fungus singly. *M. lacrymans* was shown not to be able to live in air rarefied to a pressure of 17 mm. mercury; its mycelium lost its viability after 10 days in such an atmosphere, while in air rarefied to 33 mm. its rate of growth was slowed down to half of that in normal air. On the other hand, the growth of *C. cerebella* was not retarded at this rarefaction, and its viability was not affected by 10 days' sojourn in air rarefied to 17 mm. The mycelium of *M. lacrymans* was killed by an exposure of one hour to a temperature of 40° C. or by 20 minutes at 60°, while *C. cerebella* withstood both tests and was only killed at temperatures over 60°. Three hours' exposure to a temperature of - 20° killed *M. lacrymans*, while *C. cerebella* remained viable after the same length of exposure to - 30°.

The embedding in concrete of wood infected with either or both of the fungi did not check the development of the rot. The mycelium of *M. lacrymans* was able to penetrate through the pores in the concrete to a depth of 1 cm., indicating that to protect timber from outside contamination the layer of concrete covering it should be over 1 cm. thick.

VANINE (S. I.). Лесная фитопатология. [Forestal phytopathology.]—
440 pp., 227 figs., Гослестехиздат [State Forestal Tech. Pub.
Office], Leningrad, 1934.

This is a somewhat condensed version of the author's previously pub-
lished text-books on forest pathology [R.A.M., xiii, p. 405] and the
decays of felled and structural timber, which has been officially adopted
by the Soviet authorities for use in the Schools of Forestry of the
U.S.S.R. The book is well produced and copiously illustrated and should
prove a handy and useful text-book for students.

[A phytopathological survey of stands tapped for turpentine in the Siverskaya forest estate.]—U.S.S.R. Central Forest. Res. Inst. Bull. 2 (Problems of Forest Protection), Leningrad, pp. 67-83, 3 figs., 3 diag., 1 graph, 1934. [English summary.]</p> <p>During a four-year survey of the pine and spruce trees utilized for turpentine extraction in the Siverskaya forest estate (near Leningrad), a number of blue-staining fungi were observed, their incidence being much higher in trees subjected to the Russian than to the German method of tapping. Where the former method is adopted, the stains may cover 30 to 80 per cent. of the tapped surface by the fourth year, whereas in the latter only the salient edges of the cuts are involved. In no case were the fungi observed to penetrate below a depth of 2 mm. in the wood. Spruces are more extensively damaged</p>

VANINK (S. I.) & VLADIMIRSKAYA (Mme N. N.). О действии некоторых газов на гребницу домовых грибов и о глубине проникновения газов в древесину. [On the action of certain gases on the mycelium of house fungi, and on the depth of penetration of gases into wood.]—*Acta Inst. Bot. Acad. Scient. U.R.P.S.S.*, Ser. iv (*Bot. Experimentalis*), Leningrad, 1934, 1, pp. 205-222, 4 figs., 1934. (German summary.)

This is a somewhat expanded account of the authors' laboratory experiments to test the possibility of controlling house fungi (*Merulius lacrymans* and *Coniophora cerebella*) in buildings by fumigation with gases and volatile substances, such as chlorine, chloro-pierin, acetic acid, etc., and also to determine the depth to which the gases and vapours of these substances penetrate into wood, a report of which has already been noticed [*R.A.M.*, xii, p. 261].

Influence of the first stages of decay on the treatment of timber with antiseptics. S. I. Vanin. *Mitt. forstl. Anst. (U. S. S. R.)* No. 47, 23-25 (in English 37-8) (1938).—Various species of wood in the initial stages of spot decay caused by wood-destroying fungi were treated at pressures of 55 cm. to 8 atm. by the complete adsorption and the Rüping methods with $ZnCl_2$ or a mixt. of cresote and black mineral oil as antiseptics to det. the effect of injury on the degree of penetration. Reddish brown colored pine wood attacked by the fungi *S. Stereum* and *Corticium* and sound timber are penetrated to the same extent by mineral and oil antiseptics. Brown-colored spruce wood attacked by *Peniophora gigantea* or by *Trametes abietis* is more permeable to oil antiseptics than is sound wood. Grayish brown stained (false heartwood) maple wood attacked by *Fomes connexus* is less permeable than sound wood. Tabulated data. John Livak

The impregnation of sapwood, heartwood and ripe wood with oleaginous antiseptics. S. I. Vanin, I. A. Bazhenova and N. G. Prihot. *Mitt. Kirov forstlich. Akad.* (U. S. S. R.) No. 40, 73-85 (in German 85-9, in English 89-7) (1937). The species examd. were: birch, alder, aspen, hornbeam, boxwood, beech, maple (I-VII), spruce (VIII), fir (IX), ash (X), pistachio (XI) and oak (XII). Samples 12 x 4 x 4 cm. were taken from the heartwood, sapwood or ripe-wood parts of a butt and impregnated with a creosote-black-mineral oil mixt. (40-60%) in an impregnation tank under 6-8 atm. by the method of full absorption. For the sapwood species (I-VII) the rate of impregnation is the same for both exterior and interior parts of the stem. The false core of the birch is less pervious than the normal wood. For the ripe-wood species (VIII, IX) the rate of impregnation of the sapwood is much higher (50-84%) than for the ripe wood. With X, XI and XII the heartwood is much less pervious than the sapwood, that of XI remaining unaffected by impregnation.
